A same Taiwan campaign

Despite substantial efforts to increase Asian economic interdependence and solidarity, the empirical results show that these did not result in much real growth or trade with one another. Intra-Asian growth engines are limited and have actually declined in importance over the past decade. The Asian-5 countries have instead turned to external engines of growth such as the US, Europe, and Japan to help drive their economies.

The empirical results also show that the US has become a more important growth engine for the others in the group and has overtaken Japan. The empirical results indicate that Japan is a more important engine for the Asia-5 than China is an engine for Asia-5. The empirical results also show that China is a less important engine for the others in the group than it is for China itself. The empirical results also show that China is a more important engine for Japan than it is for the others in the group.
